

Homework 7

- **Submit your solutions electronically on the course Gradescope site as PDF files.** If you plan to typeset your solutions, please use the \LaTeX solution template on the course web site. If you must submit scanned handwritten solutions, please use a black pen on blank white paper and a high-quality scanner app (or an actual scanner, not just a phone camera). We will mark difficult to read solutions as incorrect and move on.
- **Every homework problem must be done *individually*.** Each problem needs to be submitted to Gradescope before 6AM of the due date which can be found on the course website: <https://ecealgo.com/fa24/homeworks.html>.
- For nearly every problem, **we have covered all the requisite knowledge required to complete a homework assignment prior to the “assigned” date.** This means that there is no reason not to begin a homework assignment as soon as it is assigned. Starting a problem the night before it is due a recipe for failure.

Policies to keep in mind

- **You may use any source at your disposal**—paper, electronic, or human—but you *must* cite *every* source that you use, and you *must* write everything yourself in your own words. See the academic integrity policies on the course web site for more details.
- **Being able to clearly and concisely explain your solution is a part of the grade you will receive.** Before submitting a solution ask yourself, if you were reading the solution without having seen it before, would you be able to understand it within two minutes? If not, you need to edit. Images and flow-charts are very useful for concisely explain difficult concepts.

See the course web site (<https://ecealgo.com/fa24>) for more information.

If you have any questions about these policies,
please don't hesitate to ask in class, in office hours, or on Piazza.

Extra Instructions Solutions to a dynamic programming problem have (at minimum) three things:

- A recurrence relation
- A *brief* description of what your recurrence function represents and what each case represents.
- A *brief* description of the memory element/storage and how it's filled in.

1. Assume we have a list of nuts $N = [n_1 .. n_k]$ and a list of bolts $B = [b_1 .. b_k]$, where each nut and bolt is of unique size. Each nut matches exactly one bolt and vice versa. The nuts and bolts are visually indistinguishable, therefore you cannot directly compare a pair of bolts or a pair of nuts. However, you can compare a bolt to a nut by trying to fit them, at which point you'll find if the pair is too loose, too tight, or perfectly fit. In addition, you are also given an $O(1)$ oracle $M(S)$ which will return the median of S , where $S \subseteq N$. Describe an $O(k \log k)$ algorithm that matches each nut to each bolt.

2. There is a group of n dogs labeled from 1 to n where each dog has a different level of loudness and a different level of smartness. You are given an array, denoted as *clever*, where $\text{clever}[i] = [a_i, b_i]$ indicates that a_i is smarter than b_i and an integer array where $\text{quite}[i]$ denotes the quietness of the i^{th} dog. You can assume all the input data is correct.

Describe and analyze an algorithm that will output an integer array where $\text{ret}[x] = y$ if y is the least quiet dog among all dogs who have equal or more intelligence than dog x .

3. You are given a directed graph $G = (V, E)$ with positive length edges, as well as two vertices s and t . An edge $e \in E$, is considered bad if the cost of all walks from s to t that uses e costs at least 3β , where β is the length of the shortest path from s to t . Describe an algorithm that computes all the *bad* edges in G . Slower algorithms would earn 60% of the total points.

4. In the euclidean traveling-salesman problem, we are given a set of n points in the plane, and we wish to find the shortest closed tour that connects all n points. The figure above shows the solution to a 7-point problem. The general problem is NP-hard, and its solution is therefore believed to require more than polynomial time (we'll learn more about this in the third part of the course but for right now, this is just a bit of flavor).

J. L. Bentley has suggested that we simplify the problem by restricting our attention to bitonic tours, that is, tours that start at the leftmost point, go strictly rightward to the rightmost point, and then go strictly leftward back to the starting point. Figure 15.11(b) shows the shortest bitonic tour of the same 7 points. In this case, a polynomial-time algorithm is possible.

Describe an $O(n^2)$ -time algorithm for determining an optimal bitonic tour. You may assume that no two points have the same x -coordinate and that all operations on real numbers take unit time. (Hint: Scan left to right, maintaining optimal possibilities for the two parts of the tour.)
