Merge Sort splits into 2 (roughly) equal sized arrays. Can we do better by splitting into more than 2 arrays? Say k arrays of size n/k each?

ECE-374-B: Lecture 10 - Divide and Conquer Algorithms

Instructor: Nickvash Kani

University of Illinois at Urbana-Champaign

Merge Sort splits into 2 (roughly) equal sized arrays. Can we do better by splitting into more than 2 arrays? Say k arrays of size n/k each?

Quick Sort

- 1. Pick a pivot element from array
- 2. Split array into 3 subarrays: those smaller than pivot, those larger than pivot, and the pivot itself.
- 3. Recursively sort the subarrays, and concatenate them.

- 1. Pick a pivot element from array
- 2. Split array into 3 subarrays: those smaller than pivot, those larger than pivot, and the pivot itself.
- 3. Recursively sort the subarrays, and concatenate them.

- 1. Pick a pivot element from array
- 2. Split array into 3 subarrays: those smaller than pivot, those larger than pivot, and the pivot itself. Linear scan of array does it. Time is O(n)
- 3. Recursively sort the subarrays, and concatenate them.

- 1. Pick a pivot element from array
- 2. Split array into 3 subarrays: those smaller than pivot, those larger than pivot, and the pivot itself. Linear scan of array does it. Time is O(n)
- 3. Recursively sort the subarrays, and concatenate them.

- example array: 16, 12, 14, 20, 5, 3, 18, 19, 1
- worst case array: 3, 7, 5, 1, 2, 4, 6, 8

See visualizer:

https://www.hackerearth.com/practice/algorithms/sorting/quick-sort/visualize/

• Let k be the rank of the chosen pivot. Then, T(n) = T(k-1) + T(n-k) + O(n)media 6 T(n) = 2T(m2) + O(n) = O(n | ojn) Oly if the is also age suches t denest O(r) T(u) = T(0) + T(u-1) + O(u) $T(u) = T(u-1) + O(u) = n O(u) + O(u^2)$ ~ o(~)

- Let k be the rank of the chosen pivot. Then, T(n) = T(k-1) + T(n-k) + O(n)
- If $k = \lceil n/2 \rceil$ then $T(n) = T(\lceil n/2 \rceil 1) + T(\lfloor n/2 \rfloor) + O(n) \le 2T(n/2) + O(n)$. Then, $T(n) = O(n \log n)$.

- Let k be the rank of the chosen pivot. Then, T(n) = T(k-1) + T(n-k) + O(n)
- If $k = \lceil n/2 \rceil$ then $T(n) = T(\lceil n/2 \rceil 1) + T(\lfloor n/2 \rfloor) + O(n) \le 2T(n/2) + O(n)$. Then, $T(n) = O(n \log n)$.

- Let k be the rank of the chosen pivot. Then, T(n) = T(k-1) + T(n-k) + O(n)
- If $k = \lceil n/2 \rceil$ then $T(n) = T(\lceil n/2 \rceil 1) + T(\lfloor n/2 \rfloor) + O(n) \le 2T(n/2) + O(n)$. Then, $T(n) = O(n \log n)$.
- Typically, pivot is the first or last element of array. Then,

$$T(n) = \max_{1 \le k \le n} (T(k-1) + T(n-k) + O(n))$$

In the worst case T(n) = T(n-1) + O(n), which means $T(n) = O(n^2)$. Happens if array is already sorted and pivot is always first element.

Selecting in Unsorted Lists

Big problem with QuickSort is that the pivot might not be the median.

How long would it take us to find the median of an unsorted list?

Big problem with QuickSort is that the pivot might not be the median.

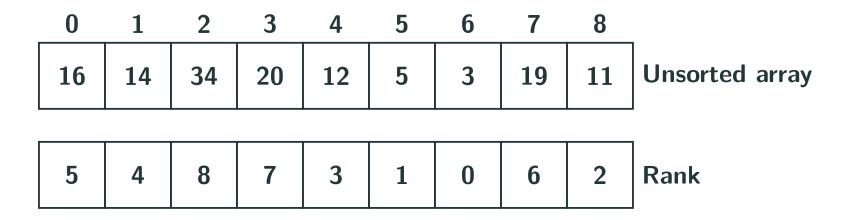

How long would it take us to find the median of an unsorted list?

Sort, then A[n/2]. Is this the optimal way?

Rank of element in an array

A: an unsorted array of *n* integers

For $0 \le j \le n-1$, element of rank j is the j + 1-th smallest element in A.

Input Unsorted array A of n integers **and** integer j **Goal** Find the j-th smallest number in A (<u>rank</u> j number)

Median: $j = \lfloor n/2 \rfloor$

Input Unsorted array A of n integers **and** integer j **Goal** Find the j-th smallest number in A (rank j number)

Median: $j = \lfloor n/2 \rfloor$

Simplifying assumption for sake of notation: elements of A are distinct

Algorithm I

- Sort the elements in *A*
- Pick *j*th element in sorted order

Time taken = $O(n \log n)$

Algorithm I

- Sort the elements in *A*
- Pick *j*th element in sorted order

Time taken = $O(n \log n)$

Do we need to sort? Is there an O(n) time algorithm?

Algorithm II

If j is small or n - j is small then

• Find *j* smallest/largest elements in *A* in *O*(*jn*) time. (How?)

3= 1/2

• Time to find median is $O(n^2)$.

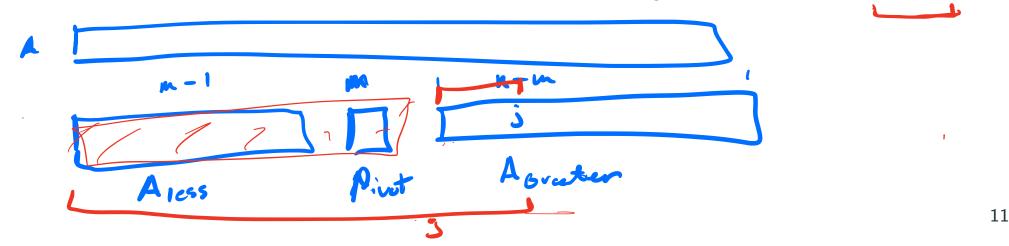

Quick select

QuickSelect

- Pick a pivot element *a* from *A*
- Partition A based on a.

 $A_{\text{less}} = \{ x \in A \mid x \le a \} \text{ and } A_{\text{greater}} = \{ x \in A \mid x > a \}$

- $|A_{\text{less}}| = j$: return *a*
- $|A_{\text{less}}| > j$: recursively find *j*th smallest element in A_{less}
- $|A_{\text{less}}| < j$: recursively find kth smallest element in A_{greater} where $k = j |A_{\text{less}}|$.

16 14 34 20 12 5 3 19

- Partitioning step: O(n) time to scan A
- How do we choose pivot? Recursive running time?

T(n) = T(n-k) + O(n)

4

- Partitioning step: O(n) time to scan A
- How do we choose pivot? Recursive running time?

Suppose we always choose pivot to be $A[\mathcal{D}]$.

- Partitioning step: O(n) time to scan A
- How do we choose pivot? Recursive running time?

Suppose we always choose pivot to be $A[\mathcal{O}]$.

Say A is sorted in increasing order and j = n. How long does this new algorithm take?

T(w) = T(w-1) + O(w)(-> $O(w^2)$)

Does this help with QuickSort?

Should we combine this with QuickSort

Should we combine this with QuickSort

Of course not! It takes $O(n^2)$ which is already the worse case of QuickSort. Need another method....

$$T(n) = T(k-1) + T(n-k) + O(n)$$

Does k need to be n/2?

$$T(n) = T(k-1) + T(n-k) + O(n)$$
Does k need to be $n/2?$
What if $k = \frac{3}{5}n?$

$$T(n) = T(\frac{3}{5}n) + T(\frac{3}{5}n) = O(n) = O(n)$$

$$O(n)$$

$$O(n$$

$$T(n) = T(k-1) + T(n-k) + O(n)$$

Does k need to be n/2? What if $k = \frac{3}{5}n$? What if $k = \frac{7}{10}n$? T(n) = T(75n) + T(3nn) + O(n) = O(n logn)

$$T(n) = T(k-1) + T(n-k) + O(n)$$

Does k need to be n/2?

What if $k = \frac{3}{5}n$? What if $k = \frac{7}{10}n$?

we only need to be able to find a rough median! How do we do that?

Median of Medians

Divide and Conquer Approach

Idea

- Break input A into many subarrays: $L_1, \ldots L_k$.
- Find median m_i in each subarray L_i .
- Find the median x of the medians m_1, \ldots, m_k .
- Intuition: The median x should be close to being a good median of all the numbers in A.
- Use x as pivot in previous algorithm.

Given an array A = [0, ..., n - 1] of *n* numbers and an index *i*, where $0 \le i \le n - 1$, find the *i*th smallest element of *A*.

For instance, assume n = 20 and i = 10.

3 2 14 6 0 16 8 9 13 12 7 17 10 1 11 15 5 18 4 19

The smallest element of rank 10 would be 10. But how do we figure that out? Do median of medians.....

Call Median-of-Medians(A, 10)

Given an array A = [0, ..., n - 1] of *n* numbers and an index *i*, where $0 \le i \le n - 1$, find the *i*th smallest element of *A*.

For instance, assume n = 20 and i = 10.

3 2 14 6 0 16 8 9 13 12 7 17 10 1 11 15 5 18 4 19

The smallest element of rank 10 would be 10. But how do we figure that out? Do median of medians.....

Call Median-of-Medians(A, 10)

First thing we need to do is find the pivot!

Given an array A = [0, ..., n - 1] of *n* numbers and an index *i*, where $0 \le i \le n - 1$, find the *i*th smallest element of *A*.

For instance, assume n = 20 and i = 10.

3 2 14 6 0 16 8 9 13 12 7 17 10 1 11 15 5 18 4 19

The smallest element of rank 10 would be 10. But how do we figure that out? Do median of medians.....

Call Median-of-Medians(A, 10)

First thing we need to do is find the pivot!

First we reorganize:

3	16	7	15
2	8	17	5
14	0	10	18
6	13	1	4
0	12	11	19

First we reorganize:

3	16	7	15
2	8	17	5
14	0	10	18
6	13	1	4
0	12	11	19

Then we sort each column:

0	8	1	4
2	9	7	5
3	12	10	15
6	13	11	18
14	16	17	19

First we reorganize:

3	16	7	15
2	8	17	5
14	0	10	18
6	13	1	4
0	12	11	19

Then we sort each column:

0	8	1	4
2	9	7	5
3	12	10	15
6	13	11	18
14	16	17	19

Still need the pivot. Find median of medians

0	8	1	4
2	9	7	5
3	12	10	15
6	13	11	18
14	16	17	19

0	8	1	4
2	9	7	5
3	12	10	15
6	13	11	18
14	16	17	19

- Call Median-of-Medians([3,12,10,15], floor(len/2) = 2)
- Can sort this in linear time.
- Get back 12.
- 12 is our new pivot!

Back to our original array! Use the pivot (=12) to break it up into two.

We know the following:

- $len(A_{Lower}) = 12$
- $len(A_{Upper}) = 7$
- Want *k* = 10

Back to our original array! Use the pivot (=12) to break it up into two.

We know the following:

- $len(A_{Lower}) = 12$
- $len(A_{Upper}) = 7$
- Want k = 10

Call Median-of-Medians(A_{Lower}, 10)

Then we do this again:

First we reorganize:

3	9	
2	7	5
6	10	4
0	1	
8	11	

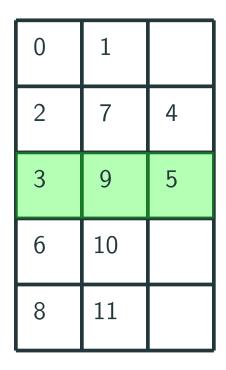

First we reorganize:

Then we sort each column:

3	9	
2	7	5
6	10	4
0	1	
8	11	

0	1	
2	7	4
3	9	5
6	10	
8	11	

0	1	
2	7	4
3	9	5
6	10	
8	11	

- Call Median-of-Medians([3,9,5], floor(n/2) = 1)
- Can sort this in linear time.
- Get back 5.
- **5** is our new pivot!

Back to our original array! Use the pivot (=5) to break it up into two (well three).

We know the following:

- $len(A_{Lower}) = 5$
- $len(A_{Upper}) = 6$
- Want k = 10 (pivot is of rank 5)

Back to our original array! Use the pivot (=5) to break it up into two (well three).

We know the following:

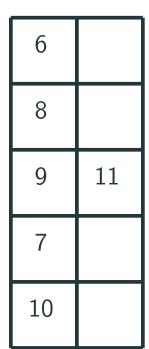

- $len(A_{Lower}) = 5$
- $len(A_{Upper}) = 6$
- Want k = 10 (pivot is of rank 5)

Call Median-of-Medians(A_{Upper} , 10 - (5 + 1) = 4)

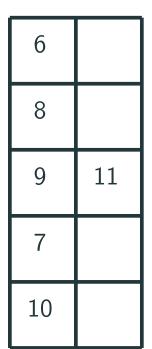

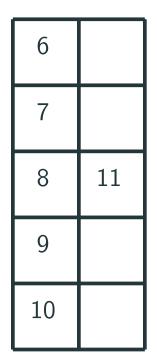

First we reorganize:

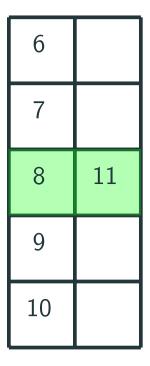

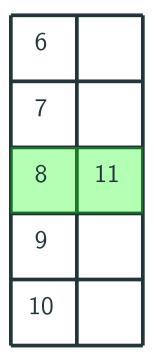

First we reorganize:

Then we sort each column:

- Call Median-of-Medians([8,11], floor(len/2) = 1)
- Can sort this in linear time.
- Get back 11.
- **11** is our new pivot!

Back to our original array! Use the pivot (=11) to break it up into partitions.

We know the following:

- $len(A_{Lower}) = 5$
- $len(A_{Upper}) = 0$
- Want k = 4 (pivot is of rank 5)

Back to our original array! Use the pivot (=11) to break it up into partitions.

We know the following:

- $len(A_{Lower}) = 5$
- $len(A_{Upper}) = 0$
- Want k = 4 (pivot is of rank 5)

Final Step!

Can sort in linear time!

Return Sorted(A[k] = A[4]) = 10

Algorithm for Selection

```
Form lists L_1, L_2, \ldots, L_{\lceil n/5 \rceil} where L_i = \{A[5i-4], \ldots, A[5i]\} 
Find median b_i of each L_i using brute-force O(i) \cdot 7_5 O(i)
Find median b of B = \{b_1, b_2, \ldots, b_{\lceil n/5 \rceil}\}
                              Partition A into A_{\text{less}} and A_{\text{greater}} using b as pivot \beta
                              if (|A_{less}|) = j return b
                              else if (|A_{less}|) > j)
        \begin{array}{c} \text{return select}(A_{\text{less}}, j) \\ \text{else} \\ \text{return select}(A_{\text{greater}}, j - |A_{\text{less}}|) \end{array} \end{array} 
                                                           T(7, ~)
```

Algorithm for Selection

```
select(A, j):
Form lists L_1, L_2, \ldots, L_{\lceil n/5 \rceil} where L_i = \{A[5i - 4], \ldots, A[5i]\}
Find median b_i of each L_i using brute-force
Find median b of B = \{b_1, b_2, \ldots, b_{\lceil n/5 \rceil}\}
Partition A into A_{less} and A_{greater} using b as pivot
if (|A_{less}|) = j return b
else if (|A_{less}|) > j
return select(A_{less}, j)
else
return select(A_{greater}, j - |A_{less}|)
```

How do we find median of *B*?

Algorithm for Selection

```
select(A, j):
Form lists L_1, L_2, \ldots, L_{\lceil n/5 \rceil} where L_i = \{A[5i - 4], \ldots, A[5i]\}
Find median b_i of each L_i using brute-force
Find median b of B = \{b_1, b_2, \ldots, b_{\lceil n/5 \rceil}\}
Partition A into A_{less} and A_{greater} using b as pivot
if (|A_{less}|) = j return b
else if (|A_{less}|) > j)
return select(A_{less}, j)
else
```

return select ($A_{greater}$, $j - |A_{less}|$)

How do we find median of B? Recursively!

Running time of deterministic median selection

$$T(n) \leq T(\lceil n/5 \rceil) + \max\{T(|A_{\text{less}}|), T(|A_{\text{greater}})|\} + O(n)$$

$$T(n) \leq T(\lceil n/5 \rceil) + \max\{T(|A_{\mathsf{less}}|), T(|A_{\mathsf{greater}})|\} + O(n)$$

From Lemma,

$$T(n) \leq T(\lceil n/5 \rceil) + T(\lfloor 7n/10 \rfloor) + O(n)$$

 $\quad \text{and} \quad$

$$T(n) = O(1) \qquad n < 10$$

$$T(n) \leq T(\lceil n/5 \rceil) + \max\{T(|A_{\mathsf{less}}|), T(|A_{\mathsf{greater}})|\} + O(n)$$

From Lemma,

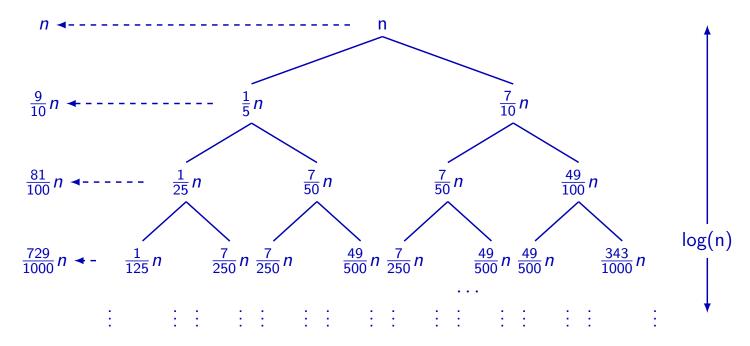

$$T(n) \leq T(\lceil n/5 \rceil) + T(\lfloor 7n/10 \rfloor) + O(n)$$

and

$$T(n) = O(1) \qquad n < 10$$

Exercise: show that T(n) = O(n)

If the workload is decreasing at every level, then total work is dominated by the root.

 $T(n) \leq T(\lceil n/5 \rceil) + T(\lfloor 7n/10 \rfloor) + O(n) = O(n)$

How would we use the median of medians approach for quicksort?

How would we use the median of medians approach for quicksort? Just use MoM if find pivot!

- Original recurrence: T(n) = T(k 1) + T(n k) + O(n)
 With MoM: T(n) = T(³/₁₀n) + T(⁷/₁₀n) + O(n) + O(n) = O(mloge)

How many Turing Award winners in the author list?

All except Vaughan Pratt! **Favorite Knuth quote**: He once warned a correspondent, "Beware of bugs in the above code; I have only proved it correct, not tried it."

Takeaway Points

- Recursion tree method and guess and verify are the most reliable methods to analyze recursions in algorithms.
- Recursive algorithms naturally lead to recurrences.
- Some times one can look for certain type of recursive algorithms (reverse engineering) by understanding recurrences and their behavior.

Problem statement: Multiplying numbers + a slow algorithm Given two large positive integer numbers b and c, with n digits, compute the number b * c.

Problem Given two *n*-digit numbers *x* and *y*, compute their product.

Grade School Multiplication

Compute "partial product" by multiplying each digit of y with x and adding the partial products.

 $3141 \\ \times 2718 \\ 25128 \\ 3141 \\ 21987 \\ 6282 \\ 8537238$

Time Analysis of Grade School Multiplication

- Each partial product: $\Theta(n)$
- Number of partial products: $\Theta(n)$
- Addition of partial products: $\Theta(n^2)$
- Total time: $\Theta(n^2)$

Multiplication using Divide and Conquer

Assume *n* is a power of 2 for simplicity and numbers are in decimal.

Split each number into two numbers with equal number of digits

•
$$b = b_{n-1}b_{n-2}...b_0$$
 and $c = c_{n-1}c_{n-2}...c_0$

•
$$b = b_{n-1} \dots b_{n/2} \dots 0 + b_{n/2-1} \dots b_0$$

•
$$b(x) = b_L x + b_R$$
, where $x = 10^{n/2}$, $b_L = b_{n-1} \dots b_{n/2}$ and $b_R = b_{n/2-1} \dots b_0$

• Similarly $c(x) = c_L x + c_R$ where $c_L = c_{n-1} \dots c_{n/2}$ and $c_R = c_{n/2-1} \dots c_0$

$$1234 \times 5678 = (12x + 34) \times (56x + 78)$$
 for $x = 100$.
= $12 \cdot 56 \cdot x^2 + (12 \cdot 78 + 34 \cdot 56)x + 34 \cdot 78$.

$$1234 \times 5678 = (100 \times 12 + 34) \times (100 \times 56 + 78)$$

= 10000 × 12 × 56
+100 × (12 × 78 + 34 × 56)
+34 × 78

Divide and Conquer for multiplication

Assume *n* is a power of 2 for simplicity and numbers are in decimal.

•
$$b = b_{n-1}b_{n-2}...b_0$$
 and $c = c_{n-1}c_{n-2}...c_0$

•
$$b \equiv b(x) = b_L x + b_R$$

where $x = 10^{n/2}$, $b_L = b_{n-1} \dots b_{n/2}$ and $b_R = b_{n/2-1} \dots b_0$

•
$$c \equiv c(x) = c_L x + c_R$$
 where $c_L = c_{n-1} \dots c_{n/2}$ and $c_R = c_{n/2-1} \dots c_0$

Divide and Conquer for multiplication

Assume *n* is a power of 2 for simplicity and numbers are in decimal.

Therefore, for $x = 10^{n/2}$, we have

$$bc = b(x)c(x) = (b_L x + b_R)(c_L x + c_R)$$

= $b_L c_L x^2 + (b_L c_R + b_R c_L)x + b_R c_R$
= $10^n b_L c_L + 10^{n/2} (b_L c_R + b_R c_L) + b_R c_R$

$$bc = 10^{n}b_{L}c_{L} + 10^{n/2}(b_{L}c_{R} + b_{R}c_{L}) + b_{R}c_{R}$$

4 recursive multiplications of number of size n/2 each plus 4 additions and left shifts (adding enough 0's to the right)

$$bc = 10^{n}b_{L}c_{L} + 10^{n/2}(b_{L}c_{R} + b_{R}c_{L}) + b_{R}c_{R}$$

4 recursive multiplications of number of size n/2 each plus 4 additions and left shifts (adding enough 0's to the right)

$$T(n) = 4T(n/2) + O(n)$$
 $T(1) = O(1)$

$$bc = 10^{n}b_{L}c_{L} + 10^{n/2}(b_{L}c_{R} + b_{R}c_{L}) + b_{R}c_{R}$$

4 recursive multiplications of number of size n/2 each plus 4 additions and left shifts (adding enough 0's to the right)

$$T(n) = 4T(n/2) + O(n)$$
 $T(1) = O(1)$

 $T(n) = \Theta(n^2)$. No better than grade school multiplication!

Faster multiplication: Karatsuba's Algorithm

Carl Friedrich Gauss: 1777–1855 "Prince of Mathematicians"

Observation: Multiply two complex numbers: (a + bi) and (c + di)

$$(a+bi)(c+di) = ac - bd + (ad + bc)i$$

Carl Friedrich Gauss: 1777–1855 "Prince of Mathematicians"

Observation: Multiply two complex numbers: (a + bi) and (c + di)

$$(a+bi)(c+di) = ac - bd + (ad + bc)i$$

How many multiplications do we need?

Carl Friedrich Gauss: 1777–1855 "Prince of Mathematicians"

Observation: Multiply two complex numbers: (a + bi) and (c + di)

$$(a+bi)(c+di) = ac - bd + (ad + bc)i$$

How many multiplications do we need?

Only 3! If we do extra additions and subtractions. Compute ac, bd, (a + b)(c + d). Then

Gauss technique for polynomials

$$p(x) = ax + b$$
 and $q(x) = cx + d$.

$$p(x)q(x) = acx^2 + (ad + bc)x + bd.$$

Gauss technique for polynomials

$$p(x) = ax + b$$
 and $q(x) = cx + d$.

$$p(x)q(x) = acx^2 + (ad + bc)x + bd.$$

$$p(x)q(x) = acx^2 + ((a+b)(c+d) - ac - bd)x + bd.$$

$$bc = b(x)c(x) = (b_L x + b_R)(c_L x + c_R)$$

$$bc = b(x)c(x) = (b_L x + b_R)(c_L x + c_R)$$

= $b_L c_L x^2 + (b_L c_R + b_R c_L)x + b_R c_R$

$$bc = b(x)c(x) = (b_L x + b_R)(c_L x + c_R)$$

= $b_L c_L x^2 + (b_L c_R + b_R c_L)x + b_R c_R$
= $(b_L * c_L)x^2 + ((b_L + b_R) * (c_L + c_R) - b_L * c_L - b_R * c_R)x$
+ $b_R * c_R$

$$bc = b(x)c(x) = (b_L x + b_R)(c_L x + c_R)$$

= $b_L c_L x^2 + (b_L c_R + b_R c_L)x + b_R c_R$
= $(b_L * c_L)x^2 + ((b_L + b_R) * (c_L + c_R) - b_L * c_L - b_R * c_R)x$
+ $b_R * c_R$

Recursively compute only $b_L c_L$, $b_R c_R$, $(b_L + b_R)(c_L + c_R)$.

$$bc = b(x)c(x) = (b_L x + b_R)(c_L x + c_R)$$

= $b_L c_L x^2 + (b_L c_R + b_R c_L)x + b_R c_R$
= $(b_L * c_L)x^2 + ((b_L + b_R) * (c_L + c_R) - b_L * c_L - b_R * c_R)x$
+ $b_R * c_R$

Recursively compute only $b_L c_L$, $b_R c_R$, $(b_L + b_R)(c_L + c_R)$.

Time Analysis Running time is given by

$$T(n) = 3T(n/2) + O(n)$$
 $T(1) = O(1)$

which means $T(n) = O(n^{\log_2 3}) = O(n^{1.585})$

Schönhage-Strassen 1971: $O(n \log n \log \log n)$ time using Fast-Fourier-Transform (FFT)

Martin Fürer 2007: $O(n \log n 2^{O(\log^* n)})$ time

Conjecture: There is an $O(n \log n)$ time algorithm.
