1. Suppose we are given both an undirected graph $G$ with weighted edges and a minimum spanning tree $T$ of $G$.

(a) Describe an efficient algorithm to update the minimum spanning tree when the weight of one edge $e \in T$ is decreased.

(b) Describe an efficient algorithm to update the minimum spanning tree when the weight of one edge $e \notin T$ is increased.

(c) Describe an efficient algorithm to update the minimum spanning tree when the weight of one edge $e \in T$ is increased.

(d) Describe an efficient algorithm to update the minimum spanning tree when the weight of one edge $e \notin T$ is decreased.

In all cases, the input to your algorithm is the edge $e$ and its new weight; your algorithms should modify $T$ so that it is still a minimum spanning tree. Of course, we could just recompute the minimum spanning tree from scratch in $O(|E| + |V| \log |V|)$ time, but you can do better.

2. Let $G = (V, E)$ be an undirected graph where each edge has a weight from the set $\{1, 10, 25\}$. Describe a linear-time algorithm to find an MST of $G$.
