• You can do hard things! Grades do matter, but not as much as you may think, but then life is uncertain anyway, so what.

• **Don't cheat.** The consequence for cheating is far greater than the reward. Just try your best and you'll be fine.

• **Please read the entire exam before writing anything.** There are 6 problems and most have multiple parts.

• This is a closed-book exam. At the end of the exam, you'll find a multi-page cheat sheet. *Do not tear out the cheat sheet!* No outside material is allowed on this exam.

• You should write your answers legibly and in the space given for the question. Overly verbose answers will be penalized.

• Scratch paper is available on the back of the exam. *Do not tear out the scratch paper!* It messes with the auto-scanner.

• **You have 75 minutes (1.25 hours) for the exam.** Manage your time well. *Do not spend too much time on questions you do not understand and focus on answering as much as you can!*

• Make sure you *use the time well to think, be precise, and show as much work as possible.*
Problem 1 [10 points]

For each of the following statements, answer if it is True or False. Use the table at the bottom to mark your choices.

i. Dijkstra’s algorithm works well on graphs with negative edge weights provided there is no negative length cycle.

ii. A problem can either be NP-Complete or NP-Hard but not both.

iii. If $P = NP$ then every NP-Complete problem can be solved in polynomial time.

iv. Graph 2-Coloring can be decided in linear time.

v. The set of all programs is larger than the set of all languages.

vi. Every undecidable language is also unrecognizable.

vii. If language $L$ is undecidable then either $L$ or $\overline{L}$ is unrecognizable.

viii. If using an Oracle for problem $X$, one can obtain a decider for the $\text{Halt}_{TM}$ then $X$ is decidable.

ix. If a barber shaves everyone who doesn’t shave themselves then the barber shaves themselves.

x. If a graph is 3-colorable then it has 3 independent sets.

Problem 2 [10 points]

Given a directed graph $G = (V, E)$ with non-negative edge lengths $l(e), e \in E$ and a node $s \in V$, describe an algorithm to find the length of a shortest cycle containing the node $s$. 
Problem 3 [10 points]

Formally prove or disprove the following statement. There is no program that always stops and solves the halting problem.
Problem 4 [20 points]

The 4-Set-Packing problem is defined as follows.

- Inputs: A collection of $m$ sets $S = \{S_1, S_2, \ldots, S_m\}$ such that $|S_i| = 4 \ \forall i \in \{1, \ldots, m\}$ and an integer $k$.
- Output: True if there exists a disjoint subcollection $L \subseteq S$ of size $k$. False otherwise.
  Note: Disjoint subcollection means no individual element belongs to two different sets in it.

The 3-Dimensional-Matching problem is defined as follows.

- Inputs: Three disjoint sets $X, Y$ and $Z$ of $n$ elements each, and a set of triplets $T \subseteq X \times Y \times Z$.
- Output: True if there exist disjoint triplets from $T$ whose union is $X \cup Y \cup Z$. False otherwise.

Given 3-Dimensional Matching is NP-Complete, show that 4-Set-Packing is NP-Complete.
Problem 5 [14 points]

a. A quasi-satisfying assignment (quasiSAT) for a 3CNF boolean formula \( \phi \) is an assignment of truth values to the variables such that at most one clause in \( \phi \) does not contain a True literal. Prove that it is \textbf{NP-Complete} to determine whether a given 3CNF boolean formula has a quasi-satisfying assignment or not.
b. Show that the Hamiltonian Cycle problem for undirected graphs is NP-Complete. Note: You may use that Hamiltonian Cycle problem for directed graphs is NP-Complete.
Problem 6 [10 points]

Identify the errors in the following proofs.

a. Define the following problems.

- **DFA-Accepts**
  Inputs: A DFA $D$ and a string $w$. Output: True if $w \in L(D)$. False otherwise.

- **NFA-Accepts**
  Inputs: A NFA $N$ and a string $w$. Output: True if $w \in L(N)$. False otherwise.

Note the following.

- **DFA-Accepts** is in $P$ as there is a single execution path for $w$ on $D$.
- Its highly unlikely that **NFA-Accepts** is in $P$. Intuitively, there are exponentially many ways to simulate $w$ on $N$ that makes **NFA-Accepts** NP-Hard.

Construct a solver for **NFA-Accepts** as follows.

Step 1. Convert the given NFA into an equivalent DFA.
Step 2. Now use the poly-time solver for **DFA-Accepts** to solve **NFA-Accepts**.

This implies **NFA-Accepts** which is NP-Hard has a poly-time solver implying $P = NP$. [Did we just solve the millennium problem!?]
b. Refer to the cheat sheet for the definition of the Independent Set decision problem. Consider the following decider for this problem.

\[
\text{DecideIndependentSet}(G = (V, E), k):
\]

For each \( S \subseteq V \) such that \(|S| = k\):

\[
\text{bool} \leftarrow \text{True}
\]

For every pair of two vertices \((u, v)\) from the set \( S \):

\[
\text{If there is an edge between } u \text{ and } v:
\]

\[
\text{bool} \leftarrow \text{False}
\]

If \( \text{bool} = \text{True} \):

\[
\text{return True}
\]

Else:

\[
\text{return False}
\]

The runtime of the above algorithm is \( T(n) = O\left((n^k)k^2\right) \). This implies Independent Set which is \( \text{NP-Hard} \) has a poly-time solver implying \( P = NP \). [Did we just solve the millennium problem again!?]
Problem 7 [6 points]

Prove or disprove that the Halting problem is NP-Hard.
Problem 8 [20 points]

For definitions of $A_{TM}$, $Halt_{TM}$, $HaltB_{TM}$ refer to the cheat sheet.

a. Using undecidability of $A_{TM}$, show that $HaltB_{TM}$ is undecidable.
b. Using undecidability of $\text{Halt}_{TM}$, show that the following language is undecidable.

$$\text{Reg}_{TM} = \{ \langle M \rangle | M \text{ is a TM and } L(M) \text{ is regular.} \}$$
This page is for additional scratch work!
1 Recursion

Simple recursion

- Reduction: solve one problem using the solution to another.
- Recursion: a special case of reduction - reduce problem to a smaller instance of itself (self-reduction).

Definitions:

- Problem instance of size \( n \) is reduced to one or more instances of size \( n-1 \) or less.
- For termination, problem instances of small size are solved by some other method as base cases.

Arguably the most famous example of recursion. The goal is to move \( n \) disks one at a time from the first peg to the last peg.

Pseudocode: Tower of Hanoi

```
Hanoi (n, src, dest, tmp):
    if (n > 0) then
        Hanoi (n-1, src, tmp, dest)
        Move disk from src to dest
        Hanoi (n-1, tmp, dest, src)
```

Recurrences

Suppose you have a recurrence of the form \( T(n) = rT(n/c) + f(n) \).

The master theorem gives a good asymptotic estimate of the recurrence. If the work at each level is:

- Decreasing: \( rf(n/c) = \alpha f(n) \) where \( \alpha < 1 \) \( T(n) = O(f(n)) \)
- Equal: \( rf(n/c) = f(n) \) \( T(n) = O(f(n) \cdot \log_n(n)) \)
- Increasing: \( rf(n/c) = Kg(n) \) where \( K > 1 \) \( T(n) = O(n^{\log_c K}) \)

Some useful identities:

- Sum of integers: \( \sum_{k=1}^{n} k = \frac{n(n+1)}{2} \)
- Geometric series closed-form formula: \( \sum_{k=0}^{n} ar^k = \frac{1-r^{n+1}}{1-r} \)
- Logarithmic identities: \( \log(ab) = \log a + \log b \), \( \log(a/b) = \log a - \log b \), \( \log(a^b) = b \log a \) if \( a, b, c > 1 \).

Backtracking

Backtracking is the algorithm paradigm involving guessing the solution to a single step in some multi-step process and recursing backwards if it doesn’t lead to a solution. For instance, consider the longest increasing subsequence (LIS) problem. You can either check all possible subsequences:

Pseudocode: LIS - Naive implementation

```
alglisNaive(A[1..n]):
    maxmax = 0
    for each subsequence B of A do
        if B is increasing and |B| > maxmax then
            maxmax = |B|
    return maxmax
```

On the other hand, we don’t need to generate every subsequence; we only need to generate the subsequences that are increasing:

Pseudocode: LIS - Backtracking

```
LIS_smaller(A[1..n], x):
    if n = 0 then return 0
    max = LIS_smaller(A[1..n-1], x)
    if A[n] < x then
        max = max (max + 1 + LIS_smaller(A[1..(n-1)], A[n]))
    return max
```

Divide and conquer

Divide and conquer is an algorithm paradigm involving the decomposition of a problem into the same subproblem, solving them separately and combining their results to get a solution for the original problem.

<table>
<thead>
<tr>
<th>Algorithm</th>
<th>Runtime</th>
<th>Space</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mergesort</td>
<td>( O(n \log n) )</td>
<td>( O(n \log n) )</td>
</tr>
<tr>
<td>Quicksort</td>
<td>( O(n^2) ) if using MoM</td>
<td>( O(n) )</td>
</tr>
</tbody>
</table>

We can divide and conquer multiplication like so:

\[
b \times c = 10^n b_L c_L + 10^{n/2} (b_L c_R + b_R c_L) + b_R c_R.
\]

We can rewrite the equation as:

\[
b \times c = (b_L x + b_R) (c_L x + c_R) = (b_L c_L) x^2 + ((b_L + b_R)(c_L + c_R) - b_L c_L - b_R c_R)x + b_R c_R.
\]

Its running time is \( O(n \log^2 3) = O(n^{1.585}) \).

Linear time selection

The median of medians (MoM) algorithms give an element that is larger than \( \frac{2}{3} \)’s and smaller than \( \frac{1}{3} \)’s of the array elements. This is used in the linear time selection algorithm to find element of rank \( k \).

Pseudocode: Quicksort with median of medians

```
Median-of-medians (A, a)
sublists = [A[j:j+i] for j = 0, 5, ..., len(A)]
medians = list(sublists[len(sublist)/2])
for sublist in sublists:
    pivot = Median-of-medians (medians, len(sublist)/2)
```

Pseudocode: Karatsuba’s algorithm

```
Karatsuba’s algorithm
```

```
Backtracking is the algorithm paradigm involving guessing the solution to a single step in some multi-step process and recursing backwards if it doesn’t lead to a solution. For instance, consider the longest increasing subsequence (LIS) problem. You can either check all possible subsequences:

Pseudocode: LIS - Naive implementation

```
alglisNaive(A[1..n]):
    maxmax = 0
    for each subsequence B of A do
        if B is increasing and |B| > maxmax then
            maxmax = |B|
    return maxmax
```

On the other hand, we don’t need to generate every subsequence; we only need to generate the subsequences that are increasing:

Pseudocode: LIS - Backtracking

```
LIS_smaller(A[1..n], x):
    if n = 0 then return 0
    max = LIS_smaller(A[1..n-1], x)
    if A[n] < x then
        max = max (max + 1 + LIS_smaller(A[1..(n-1)], A[n]))
    return max
```
Dynamic programming (DP) is the algorithm paradigm involving the computation of a recursive backtracking algorithm iteratively to avoid the recomputation of any particular subproblem.

## Longest increasing subsequence
The longest increasing subsequence problem asks for the length of a longest increasing subsequence in an unordered sequence, where the sequence is assumed to be given as an array. The recurrence can be written as:

\[
LIS(i, j) = \begin{cases} 
0 & \text{if } i = 0 \\
LIS(i - 1, j) & \text{if } A[i] \geq A[j] \\
\max \{LIS(i - 1, j), 1 + LIS(i - 1, i)\} & \text{else}
\end{cases}
\]

Pseudocode: LIS - DP

**LIS-Iterative**($A[1..n]$):

1. $A[n + 1] = \infty$
2. for $j \leftarrow 0$ to $n$
   - if $\forall i \leq A[j]$ then $LIS[0][j] = 1$
3. for $i \leftarrow 1$ to $n - 1$
   - for $j \leftarrow i$ to $n - 1$
     - if $A[i] \geq A[j]$
       - $LIS[i, j] = LIS[i - 1, j]$
     - else
       - $LIS[i, j] = \max\{LIS[i - 1, j], 1 + LIS[i - 1, i]\}$
4. return $LIS[n, n + 1]$

### Edit distance
The edit distance problem asks how many edits we need to make to a sequence for it to become another one. The recurrence is given as:

\[
\text{Opt}(i, j) = \min\left\{\begin{array}{ll}
\alpha_{x[i], y[j]} + \text{Opt}(i - 1, j - 1), \\
\delta + \text{Opt}(i - 1, j), \\
\delta + \text{Opt}(i, j - 1)
\end{array}\right.
\]

**Base cases:** $\text{Opt}(i, 0) = \delta \cdot i$ and $\text{Opt}(0, j) = \delta \cdot j$

Pseudocode: Edit distance - DP

**EDIST**($A[1..m], B[1..n]$):

1. for $i \leftarrow 1$ to $m$ do $M[i, 0] = i\delta$
2. for $j \leftarrow 1$ to $n$ do $M[0, j] = j\delta$
3. for $i \leftarrow 1$ to $m$
   - for $j \leftarrow 1$ to $n$
     - $M[i][j] = \min\left\{\begin{array}{ll}
\text{COST}[A[i], B[j]] + M[i - 1][j - 1], \\
\delta + M[i - 1][j], \\
\delta + M[i][j - 1]
\end{array}\right.$

## 2 Graph algorithms

### Graph basics
A graph is defined by a tuple $G = (V, E)$ and we typically define $n = |V|$ and $m = |E|$. We define $(u, v)$ as the edge from $u$ to $v$. Graphs can be represented as adjacency lists or adjacency matrices though the former is more commonly used.

- **path:** sequence of distinct vertices $v_1, v_2, \ldots, v_k$ such that $(v_i, v_{i+1}) \in E$ for $1 \leq i \leq k - 1$. The length of the path is $k - 1$ (the number of edges in the path). Note: a single vertex $u$ is a path of length 0.
- **cycle:** sequence of distinct vertices $v_1, v_2, \ldots, v_k$ such that $(v_i, v_{i+1}) \in E$ for $1 \leq i \leq k - 1$ and $(v_k, v_1) \in E$. A single vertex is not a cycle according to this definition. Caveat: Sometimes people use the term cycle to also allow vertices to be repeated, we will use the term tour.
- A vertex $u$ is connected to $v$ if there is a path from $u$ to $v$.
- The connected component of $u$, $\text{con}(u)$, is the set of all vertices connected to $u$.
- A vertex $u$ can reach $v$ if there is a path from $u$ to $v$. Alternatively $v$ can be reached from $u$. Let $\text{rch}(u)$ be the set of all vertices reachable from $u$. 

Directed acyclic graphs

Directed acyclic graphs (dags) have an intrinsic ordering of the vertices that enables dynamic programming algorithms to be used on them. A topological ordering of a dag $G = (V, E)$ is an ordering $\prec$ on $V$ such that if $(u, v) \in E$ then $u \prec v$.

**Directed acyclic graphs**

**Pseudocode: Kahn’s algorithm**

```
Kahn(G(V, E), n): 
  toposort ← empty list 
  for v ∈ V do 
    in(v) ← |{u | u → v ∈ E}| 
  while V has in(v) > 0 do 
    v ← in(v) > 0 
    Add v to end of toposort 
    Remove v from V 
  for v ∈ V do 
    in(v) ← in(v) − 1 
  return toposort
```

Running time: $O(n + m)$

- A dag may have multiple topological sorts.
- A topological sort can be computed by DFS, in particular by listing the vertices in decreasing post-visit order.

DFS and BFS

**Pseudocode: Explore (DFS/BFS)**

```
Explore(G, u): 
  for i ← 1 to n do 
    Visited[i] ← False 
  Add u to ToExplore and to S 
  Visited[u] ← True 
  Make tree T with root as u 
  while B is not empty do 
    Remove node x from B 
    for each edge (x, y) in Adj(x) do 
      if Visited[y] = False 
        Visited[y] ← True 
        Add y to B, S, T (with x as parent)
```

Pre and post numbering aids in analyzing the graph structure. By looking at the numbering, we can tell if an edge $(u, v)$ is a:
- Forward edge: $\text{pre}(u) < \text{pre}(v) < \text{post}(v) < \text{post}(u)$
- Backward edge: $\text{pre}(v) < \text{pre}(u) < \text{post}(u) < \text{post}(v)$
- Cross edge: $\text{pre}(u) < \text{post}(u) < \text{pre}(v) < \text{post}(v)$

**Strongly connected components**

- Given $G$, $u$ is strongly connected to $v$ if $u \in \text{rch}(v)$ and $v \in \text{rch}(u)$.
- A maximal group of $G$'s vertices that are all strongly connected to one another is called a strong component.

**Pseudocode: Metagraph - linear time**

```
Metagraph(G(V, E)): 
  Compute rev(G) by brute force ordering ← reverse postordering of V in rev(G)
  by DFS(rev(G), x) for any vertex $x$ 
  Mark all nodes as unvisited 
  for each u in ordering do 
    if u is not visited and u ∈ V then 
      S_u ← nodes reachable by u by DFS(G, u) 
      Output S_u as a strongly connected component 
      $G(V, E) ← G - S_u$
```

Running time: $\Theta(n^3)$

Shortest paths

**Dijkstra’s algorithm:**

Find minimum distance from vertex $s$ to all other vertices in graphs without negative weight edges.

**Pseudocode: Dijkstra**

```
for $v \in V$ do 
  d(v) ← $\infty$
X ← $E$
X[0] ← $s$
X[n] ← $\emptyset$
for i ← 1 to n do 
  $v ← arg min_{u \in V - X} d(u)$
X ← X ∪ {v}
for u in Adj(v) do 
  d(u) ← min{(d(u), d(v) + $\ell(u, v)$)}
return d
```

Running time: $O(m + n \log n)$ (if using a Fibonacci heap as the priority queue)

**Bellman-Ford algorithm:**

Find minimum distance from vertex $s$ to all other vertices in graphs without negative cycles. It is a DP algorithm with the following recurrence:

$$d(v, k) = \begin{cases} 
0 & \text{if } v = s \text{ and } k = 0 \\
\min \{d(u, k - 1) + \ell(u, v)\} & \text{else}
\end{cases}$$

Base cases: $d(s, 0) = 0$ and $d(v, 0) = \infty$ for all $v \neq s$.

**Pseudocode: Bellman-Ford**

```
for each $v \in V$ do 
  d(v) ← $\infty$
for k ← 1 to n - 1 do 
  for each $v \in V$ do 
    for each edge $(u, v) \in E$ do 
      d(v) ← min{d(v), d(u) + $\ell(u, v)$}
return d
```

Running time: $O(nm)$

**Floyd-Warshall algorithm:**

Find minimum distance from every vertex to every vertex in a graph without negative edges. It is a DP algorithm with the following recurrence:

$$d(i, j, k) = \begin{cases} 
0 & \text{if } i = j \\
\min \{d(i, j, k - 1) + \ell(i, j), d(i, k, k - 1) + \ell(k, j)\} & \text{else}
\end{cases}$$

Then $d(i, j, n - 1)$ will give the shortest-path distance from $i$ to $j$.

**Pseudocode: Floyd-Warshall**

```
Metagraph(G(V, E)): 
for i ∈ V do 
  for j ∈ V do 
    $d(i, j, 0) ← \ell(i, j)$
    (* $\ell(i, j) ← \infty$ if $(i, j) \notin E$, 0 if $i = j$ *)
  for k ← 0 to n - 1 do 
    for i ∈ V do 
      for j ∈ V do 
        $d(i, j, k) ← \min\{d(i, j, k - 1), d(i, k, k - 1) + \ell(k, j)\}$
      for v ∈ V do 
        if $d(i, v, n - 1) < 0$ then 
          return "exists negative cycle in $G$
```

Running time: $\Theta(n^3)$
Turing Machines

Turing machine is the simplest model of computation:
- Input written on (infinite) one sided tape.
- Special blank characters.
- Finite state control (similar to DFA).
- Every step: Read character under head, write character out, move the head right or left (or stay).
- Every TM $M$ can be encoded as a string $⟨M⟩$.

Transition Function: $δ : Q × Γ → Q × Γ × {←, →, □}$
- $q$: current state.
- $c$: character under tape head.
- $p$: new state.
- $←$: Move tape head left.
- $→$: Move tape head right.
- $□$: New cell is blank.

Complexity Classes

Computational Complexity Classes

- Turing-unrecognizable
  - Undecidable
  - Semi-Decidable (recursively-enumerable, recognizable, Turing-acceptable/recognizable, partially-decidable)
  - Decidable (Recursive)
  - Context-Free
    - Regular
  - Context-Sensitive
    - Decidable
- Turing-recognizable
  - P
  - NP
  - co-NP
  - NPC
  - NP-Hard
  - EXP
  - PSPACE
  - P
  - NP
  - co-NP
  - NPC
  - NP-Hard

Algorithmic Complexity Classes (assuming $P ≠ NP$)

- Undecidable
  - $NP$-Hard
  - $NP$-Complete
  - $PSPACE$
  - $EXP$
  - $P$
  - $NP$

Reductions

A general methodology to prove impossibility results.
- Start with some known hard problem $X$
- Reduce $X$ to your favorite problem $Y$

Karp Reduction:
- Sample undecidable problems
- Sample NP-complete problems

CircuitSAT: Given a boolean circuit, are there any input values that make the circuit output “true?”
3SAT: Given a boolean formula in conjunctive normal form, with exactly three distinct literals per clause, does the formula have a satisfying assignment?
IndependentSet: Given an undirected graph $G$ and integer $k$, what is there a subset of vertices $S ⊆ V(G)$ that have no edges among them?
CLIQUE: Given an undirected graph $G$ and integer $k$, is there a complete complete subgraph of $G$ with more than $k$ vertices?
$k$-PARTITION: Given a set $X$ of $kn$ positive integers and an integer $k$, can $X$ be partitioned into $n$, $k$-element subsets, all with the same sum?
3COLOR: Given an undirected graph $G$, can its vertices be colored with three colors, so that every edge touches vertices with two different colors?
HamiltonianPath: Given graph $G$ (either directed or undirected), is there a path in $G$ that visits every vertex exactly once?
HamiltonianCycle: Given a graph $G$ (either directed or undirected), is there a cycle in $G$ that visits every vertex exactly once?
LongestPath: Given a graph $G$ (either directed or undirected, possibly with weighted edges) and an integer $k$, does $G$ have a path of length at least $k$?

Sample undecidable problems

- $A_{TM} = \{⟨M, w⟩ | M$ is a TM and $M$ accepts on $w\}$
- $A_{TM} = \{⟨M, w⟩ | M$ is a TM and $M$ halts on input $w\}$
- $A_{TM} = \{⟨M, w⟩ | M$ is a TM and $B$ halts on blank input $w\}$
- $A_{TM} = \{⟨M, w⟩ | M$ is a TM and $L(M) = ∅\}$
- $A_{TM} = \{⟨M_A, M_B⟩ | M_A and M_B are TM’s and $L(M_A) = L(M_B)\}$
